ABSTRACT

As part of an ongoing exploration of marine invertebrates as a source of new antimicrobial peptides, hemocyte extracts from the red king crab, *Paralithodes camtschaticus* were studied. Three cationic cysteine (Cys)-rich peptides, named paralithocins 1-3, were isolated by bioassay guided purification and their amino acid sequences determined by Edman degradation and expressed sequences tag analysis. Disulfide bond mapping was performed by high resolution tandem mass spectrometry. The peptides (38-51 amino acids in length) share a unique Cys motif composed of eight Cys, forming four disulfide bridges with a bond connectivity of (Cys relative position) Cys1-Cys8, Cys2-Cys6, Cys3-Cys5, and Cys4-Cys7, a disulfide arrangement that has not been previously reported among antimicrobial peptides. Thus, paralithocins 1-3 may be assigned to a previously unknown family of antimicrobial peptides within the group of Cys-rich antimicrobial peptides. Although none of the isolated peptides displayed antimicrobial activity against the target strains *Escherichia coli*, *Pseudomonas aeruginosa* or *Staphylococcus aureus*, they inhibited the growth of several marine bacterial strains with minimal inhibitory concentrations (MIC) in the 12.5-100 μ M range. These findings corroborate the hypothesis that marine organisms are a valuable source for discovering bioactive peptides with genuine structural motifs.

Antimicrobial peptides (AMPs) are oligopeptides that inhibit bacterial growth *in vitro* under physiological conditions. They are considered to be an important part of the innate immune system in all species, including vertebrates and invertebrates.^{1, 2} Due to their lack of T- and B-cell repertoire, invertebrates depend on AMPs and other innate immune factors/mechanisms to combat invading pathogens. The importance of AMPs for survival during microbial challenge has been well documented in several invertebrate species, including the fruit fly, *Drosophila melanogaster*,³ the whiteleg shrimp, *Litopenaeus vannamei*,⁴⁻⁶ and the Pacific oyster *Crassostrea gigas*.⁷ Upon a microbial challenge, increased levels of AMPs are due to either increased ribosomal translation or cleavage of larger proteins (already present, having other physiological functions) of which the AMPs are an integral part.^{8, 9} Beside their function as genetically coded antimicrobials, evidence suggests that AMPs may alter membrane properties or interact with receptors to influence e.g. cytokine release, chemotaxis, wound healing, angiogenesis, and antigen presentation.¹⁰⁻¹²

Most AMPs share some common features; they constitute less than 100 amino acids (aa), are positively charged, and amphipathic.¹³ A finer classification is challenging, but some broad groups exist: 1) amphipathic peptides with a linear α -helix structure; 2) peptides with β -sheets and/or extended or loop structures, often stabilized by disulfide bridges; 3) peptides with a high proportion of one or more aa (most often Pro, Arg, Gly, Trp, and/or His); and 4) peptides containing one or more D-aa and/or modified aa (e.g. brominated Trp).^{10, 14} Marine invertebrates have proven to be a promising source for discovery of bioactive peptides and numerous AMPs have been characterized from crustacean hemolymph/hemocytes, most of them Cys-rich.^{15, 16} *Crustacea* is an arthropod subphylum comprising a diverse group of animals, including species with both ecological and economic importance. In terms of AMPs, there has been a particular emphasis on the characterization of the AMP families of penaeidins and crustins.^{15, 17} The

penaeidins, consisting of a Pro-Arg rich N-terminal region and a cysteine-containing C-terminal region, have only been detected in shrimp (Penaidae) species.¹⁸ The C-terminal part contains three disulfide bridges having a Cys motif of Cys1-Cys3, Cys2-Cys5, and Cys4-Cys6 (the italic numbers corresponds to the relative positions of Cys throughout the peptide chain).^{19, 20} The crustin peptide family is defined as AMPs of ca. 7-14 kDa in size, containing 8-12 Cys, with a characteristic four-disulfide core-containing whey acidic protein (WAP) domain in the C-terminal part. In contrast to the penaeidins, the crustins seem to be widespread throughout the entire crustacean subphylum,²¹ and even present in other arthropod subphyla.²² In addition to penaeidins and crustins, numerous other AMPs have been discovered in crustaceans.¹⁵ Recently, panusin, a β -defensin-like AMP containing six Cys with Cys1-Cys5, Cys2-Cys4, and Cys3-Cys6 connectivity was discovered.²³

Although the disulfide bridges are not essential for biological activity in some disulfide-containing AMPs,²⁴⁻²⁶ a stable tertiary structure is usually imperative for proper biological function and stability of disulfide-rich peptides.²⁷ A peptide with n Cys have i possible arrangements for disulfide bridge connectivity:

$$i = \frac{n!}{(n/2)!2^{n/2}}$$

Determining the correct Cys pair bridging is crucial to predict the correct peptide tertiary structure. Three methods are commonly used in order to determine the disulfide connectivity; NMR analysis,²⁸ X-ray crystallography,²⁹ and Edman degradation,³⁰ however, these techniques usually require a few mg of the sample material and peptides obtained from marine invertebrates are rarely isolated in such high amounts. Mass spectrometry (MS) is therefore a suitable technique for disulfide bridge connectivity studies of polypeptides, although the

structure elucidation is more cumbersome compared to NMR and X-ray analysis, because manual interpretation of the spectra is required, especially if the peptide constitutes an undescribed Cys-rich motif. Several strategies can be used for disulfide connectivity determination by MS analysis either used alone or in combination with other techniques, as thoroughly reported by Tsai et al.:³¹ 1) peptide profiles are compared before and after reduction; 2) one or more partial reduction(s) and alkylation(s); 3) data analysis based on *in silico* algorithms; 4) in line reduction of Cys-Cys, and 5) labeling with disulfide selective reagents.

In a previous study,³² we detected antibacterial activity in various tissues and the hemocytes of the red king crab, *Paralithodes camtschaticus*. Later, the primary structure of a putative crustin AMP was described in the same species.¹⁶ Herein we report on the isolation and structure elucidation of three new AMPs, all containing four disulfide bridges, from the hemocytes of *P. camtschaticus*. The peptides were isolated through bioassay-guided purification and tested for activity against Gram negative and Gram positive bacteria. Their primary structures were partially elucidated through Edman amino acid sequencing and totally verified by comparison of mass spectrometry (MS/MS) data analysis of intact peptides with sequences of putative peptides derived from an expressed sequence tag (EST) library. Finally, the disulfide connectivity was elucidated by partial reduction and alkylation followed by high resolution tandem MS (HRMS/MS) analysis.

RESULTS AND DISCUSSION

Isolation of Antimicrobial Peptides from *P. camtschaticus* Hemocytes. A previous screening for antibacterial activity in the red king crab, *P. camtschaticus*, showed that hemocyte extracts contain proteinaceous compounds that possess antibacterial activity *in vitro*.³² Herein we describe the purification and characterization of three new antibacterial peptides from the hemocytes of the king crab. An extract prepared from dried hemocytes was subjected to solid phase extraction (SPE). Elution was successively performed with 10, 40, and 80% solutions of MeCN in acidified H₂O. Based on our previous results,³² and taking into account the amount of available material, we focused our attention on the 40% SPE fraction. This fraction, containing a total of 206 mg protein, was further fractionated by preparative reversed-phase high performance liquid chromatography (RP-HPLC) using a linear gradient of 0-40% MeCN. Several fractions (peaks) showed antibacterial activity against the Gram-positive bacterium *Corynebacterium glutamicum* and Gram-negative bacterium *Listonella (Vibrio) anguillarum*. The active peptides designated as P23, P30 and P34 (Figure 1) were purified to homogeneity and subjected for further analysis. As shown in Figure 1, these peptides (especially P23) constitute a major quantitative part of the compounds present in the 40% SPE eluate. Distinct UV absorbance at 280 nm during RP-HPLC (data not shown) suggests that the peptides contain tyrosine and/or tryptophan residues.

Peptide Sequencing, Amino Acid Analysis and Mass Analysis. Partial primary structure determination was performed by Edman degradation. The partial N-terminal sequences for P23 (30 residues: WQPSXSSIXDYSXGKSAXISYSGRXGXXA), P30 (30 residues: RSPPQXQYTNXAAVLXPAVYXANAYTPPXG), and P34 (29 residues:

RSQPGPTXPSSVQAILXDNRXGRSAXSYY) revealed that all peptides contained several unidentified amino acids (denoted X), most likely Cys, but otherwise no apparent homology between each other. According to amino acid analyses (Table S1), all peptides contained Cys and more basic amino acids than negatively charged amino acids, i.e. they are cationic of nature. In addition, P23 was devoid of Thr, Val, His, Phe, and Leu, but rich in Ser (ca. 23 mol%). P30 was devoid of His and Phe but rich in Pro (ca. 21 mol%), whereas P34 was devoid of Phe and relatively rich in Pro and Ser (ca. 11-16 mol% of both). The monoisotopic masses of the three peptides were determined by HRMS to be 4075.6248 (P23), 5045.1705 (P30), and 5559.4226 Da (P34), respectively. However, in each of these peptide fractions, a mass 0.98 Da above the reported value (<10% abundance compared to the main peptide) was also observed. The peptides were named paralithocin 1 (P23), paralithocin 2 (P30), and paralithocin 3 (P34) after the species from which they were isolated.

Figure 1. RP-HPLC profile of the 40% SPE eluate of a hemocyte extract from *P. camtschatica*. Peaks containing the paralithocins are labeled in the chromatogram. The dotted line shows the linear MeCN gradient (0-40%) dissolved in 0.1% TFA. The horizontal bars indicate fractions with antibacterial activity against *L. anguillarum* (dark grey) and *C. glutamicum* (hatched).

Identification of Genes and Complete Primary Structures. To identify the cDNA gene of the peptides, an EST library of the hemocytes was constructed and 384 randomly picked clones were sequenced and data from 374 were subjected to bioinformatic analyses. Cap3 sequence analyses revealed that five of 16 contigs were more redundant than the other (Table S2). The longest cDNA clones of three of the contigs (contig 2, 16 and 11) were sequenced forward and backward and consensus sequences were established (Figure S1). All three sequences coded for a signal peptide of 23 amino acids and mature peptides containing eight Cys (Figure 2). The deduced mature peptides corresponded with the partial amino acid sequences of the isolated peptides. Consensus for contig 2 (40% redundancy) and contig 16 (8% redundancy) contained open reading frames (ORF) of 62 and 71 amino acids, respectively (Figure S1A and B).

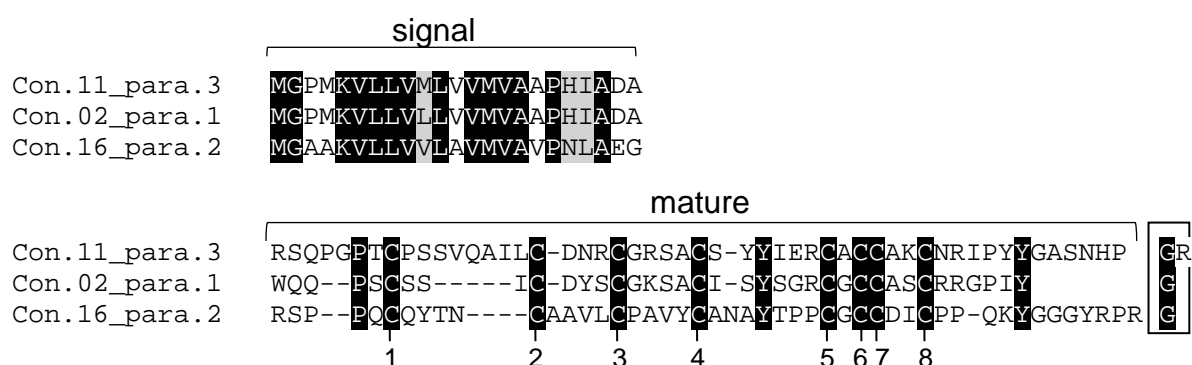

Figure 2. Alignment of the deduced peptide sequences from the EST library (contigs 11, 2 and 16) from hemocytes of the red king crab, *P. camtschatica*. The mature part of the sequences are identified as

paralithocins 3, 1 and 2, respectively. The alignment is done according to the eight cysteine arrays as indicated. Identical and strongly similar amino acids are shaded in black or grey, respectively. Pre-sequences are marked as signal-sequences and the C-terminal amino acids not present in the mature paralithocins (G and GR) are boxed.

The putative mature peptides coded were 39 and 48 aa long with theoretical monoisotopic masses of 4133.63 and 5103.17 Da (with all Cys in oxidized forms), respectively. These values deviates from the measured masses of the isolated paralithicins 1 and 2 by +58 Da, indicating the presence of additional modifications. Both sequences contain a C-terminal Gly residue, a target for peptidylglycine α -amidating monooxygenase (PAM), an enzyme contributing to C-terminal amidation of peptides.^{33,34} Cleavage of the C-terminally Gly residue and subsequent C-terminal amidation of the deduced sequences, leads to theoretical monoisotopic masses of 4075.62 and 5045.17 Da, which corresponds to the measured masses of paralithocin 1 and 2, respectively. Contig 11 (4% redundancy) contained an ORF of 76 amino acids (Figure S1C), coding for a putative mature peptide of 53 aa with a calculated monoisotopic mass of 5773.53 Da. This mass is about 214 Da above the measured mass of paralithocin 3. However, enzymatic cleavage of the C-terminal residues Gly-Arg, first by an exopeptidase and secondly by PAM, leads to a C-terminally amidated peptide with a theoretical monoisotopic mass (5559.42 Da) that corresponds completely to the experimental monoisotopic mass of paralithocin 3. Post-translational cleavage of dipeptides C-terminally (like Gly-Arg in paralithocin 3) and subsequent C-terminal amidation has been described previously in various invertebrate AMPs.³⁵⁻³⁸ A top down MALDI-TOF MS/MS analysis approach confirmed that the native amino acid sequences were identical to the putative mature peptides of the consensus contigs. Hence, this also confirmed that the C-terminal extended

amino acids were not present in the native peptides. Masses observed at +0.98 Da can be explained by paralithocin analogues having a free acid C-terminally (Table S3). Natural mixtures of C-terminally amidated and non-amidated AMPs have been described before.^{39, 40} Although the primary sequence and peptide length differ between the three mature peptides, there are some similarities. Firstly, all three peptides contain eight cysteine residues with a common cysteine pattern (C-C-C-C-C-CC-C) and sequence motif of CXCCXXC, indicating identical Cys connectivity. The isolated peptides are all cationic with isoelectric points (pI) of 8.51 (paralithocin 1), 8.50 (paralithocin 2) and 8.73 (paralithocin 3). BLAST and homology searches of the obtained oligopeptide and nucleotide sequences resulted in no overall sequence similarity to other known peptides/proteins. Comparison of the Cys pattern in the primary structure of paralithocins with other AMPs containing eight Cys residues (searches performed against various antimicrobial peptide databases) revealed a unique Cys location pattern within the paralithocins (Table 1).

Table 1. Antimicrobial Peptides Containing Four Disulfide Bridges. Adjacent Cysteines in the Cysteine Pattern Are Marked in Bold.

Cysteine-connectivity	Cysteine pattern	Representative peptide	# aa	Origin	UniProt code/ref.

Paralithocin 1 showed 55.8% and 63.2% identity to paralithocin 2 and 3, respectively, at the cDNA level. The paralithocin transcripts have been submitted to NCBI GenBank with the accession numbers MF919584 (paralithocin 1), MF919585 (paralithocin 2), and MF919586 (paralithocin 3), respectively.

Determination of Disulfide Bridge Connectivity. Peptides containing intact disulfide bridges produce y- and b-ions upon collision induced dissociation (CID) through cleavage of peptide bonds of amino acids not enveloped within the disulfide knot. Occasionally, b- and y-ions from Cys-Cys are observed as their $[b/y \pm H/SH]$ ions, but b- and y-ions formed by peptide bond cleavage of amino acids that exist within the disulfide knot are rarely observed. The strategy used in the present work was to conduct a partial reduction of the disulfide bonds and alkylation with N-ethylmaleimide (Nem), and to conduct CID experiments of the resulting peptides containing four, three, two, one, and no intact disulfides. The retention times of the partially reduced and alkylated peptides increased with their number of reduced and alkylated S–S bridges. This may be rationalized by the fact that the hydrophobic amino acids occupy the less water exposed interior of the intact peptides, but following reduction and alkylation, they were more exposed to the aqueous mobile phase used in reversed-phase chromatography, resulting in an increased non-polar surface area. Additionally, the alkylation itself introduces a slightly hydrophobic moiety to the peptide.

The total ion chromatograms (TIC) of native, partially, and totally reduced and alkylated paralithocin 1 is shown in Figure S2 and only one isomer of each reduced and alkylated peptide was observed. For native paralithocin 1, CID of $[M+5H]^{5+}$ (m/z 816.3287, $\Delta m = -0.7$ ppm) y_1^+ - y_6^+ ions were observed, in addition to $(y_7+SH)^+$, which is in accordance with Cys³² (Figure 3a).

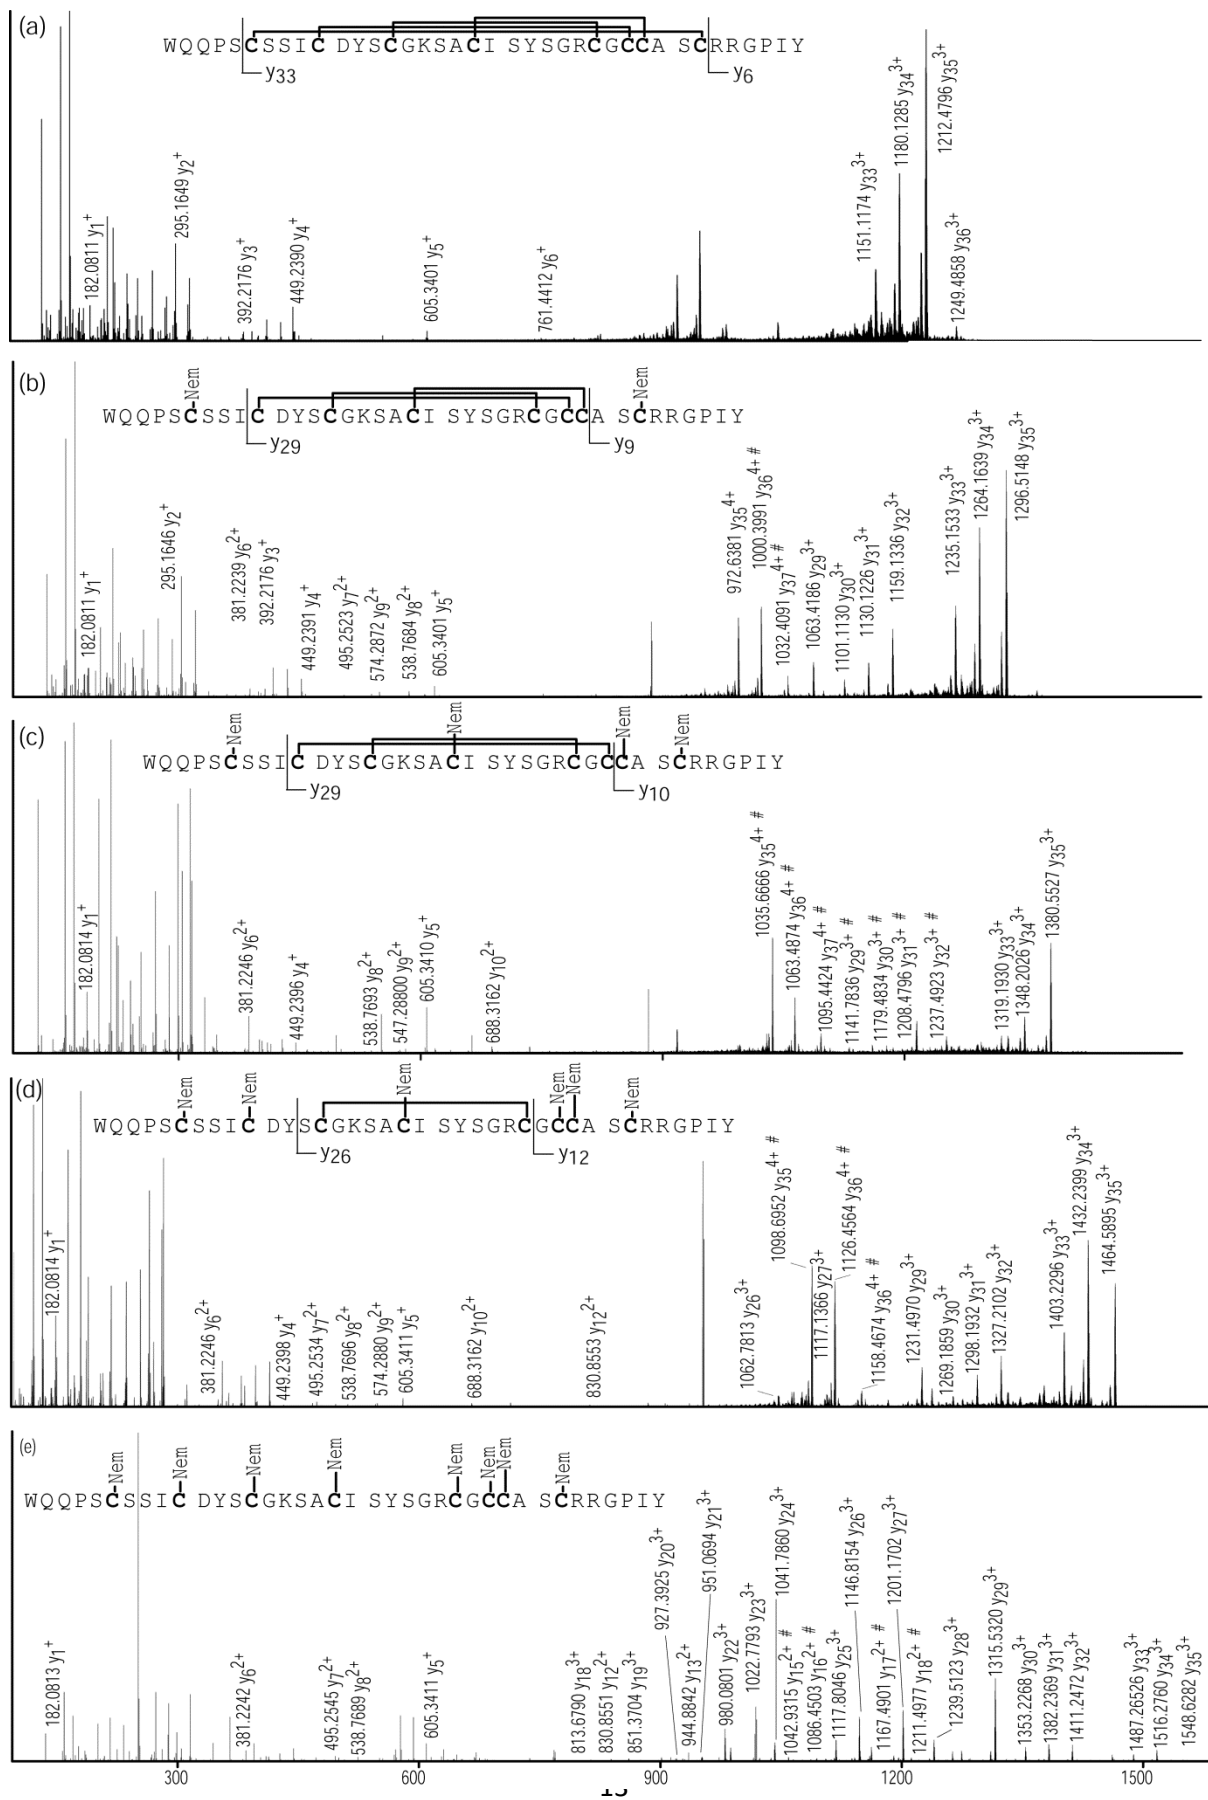

Figure 3. HRMS/MS spectra of (a) native paralithocin 1 (P23) $[M + 5H]^{5+}$ at m/z 816.3287, (b) paralithocin 1 with one reduced and alkylated Cys-Cys bond $[M + 5H]^{5+}$ at m/z 866.7509, (c) paralithocin 1 with two reduced and alkylated Cys-Cys bonds $[M + 5H]^{5+}$ at m/z 917.1749, (d) paralithocin 1 with three reduced and alkylated Cys-Cys bonds $[M + 5H]^{5+}$ at m/z 967.5953, and (e) paralithocin 1 with all Cys-Cys bonds reduced and alkylated $[M + 5H]^{5+}$ at m/z 1018.0175.

Furthermore, $y_{36}^{3+ \#}$, y_{35}^{3+} , y_{34}^{3+} , and y_{33}^{3+} were observed (# indicates additional loss of ammonia), as well as $(y_{32} + SH)^{3+}$, all in support for a Cys⁶. More ions were recorded upon CID of paralithocin 1 where one Cys-Cys was reduced and alkylated ($[M + 5H]^{5+}$ was observed at m/z 866.7509; Figure 3b). A complete series of y_1^+ to y_5^+ and y_6^{2+} to y_9^{2+} ions were recorded, indicating a reduction/alkylation of Cys³² (Cys³²-Nem). From the *N*-terminal end, the $y_{37}^{4+ \#}$ - $y_{35}^{4+ \#}$, and y_{35}^{3+} - y_{29}^{3+} ions were all observed, which indicated Cys⁶-Nem. Thus, these observations suggest a Cys⁶-Cys³² (Cys¹-Cys⁸) disulfide bridge in the native peptide. Paralithocin 1 containing four Nem groups (two reduced Cys-Cys), was observed as its $[M + 5H]^{5+}$ ion at m/z 917.1731 (Figure 3c). Its CID spectrum had peaks corresponding to y_1^+ , y_4^+ , y_5^+ , y_6^{2+} , and y_8^{2+} - y_{10}^{2+} , which was due to Cys²⁹-Nem. However, the observation of $y_{37}^{4+ \#}$ - $y_{35}^{4+ \#}$, and y_{35}^{3+} - y_{29}^{3+} , suggest that Cys¹⁰ was still disulfide bonded, leaving the remaining Cys-Nem at either of Cys¹⁴, Cys¹⁹, or Cys²⁶ (as no ions indicative of Cys²⁸-Nem were observed). The final partial reduced paralithocin 1, containing six Cys-Nem, was observed as its $[M + 5H]^{5+}$ ion at m/z 967.5953 (Figure 3d). An ion series of y_1^+ , y_4^+ , y_5^+ , y_6^{2+} - y_{10}^{2+} , and y_{12}^{2+} was observed, suggesting Cys²⁸-Nem. Furthermore, the ions y_{35}^{3+} - y_{29}^{3+} , as well as y_{27}^{3+} and y_{26}^{3+} were observed, indicating Cys¹⁰-Nem. To summarize, the observed ions indicate Cys⁶-Cys³² and Cys¹⁰-Cys²⁸ in native paralithocin 1, but as no ions were observed upon CID of paralithocin 1 with six Cys-Nem indicating the presence of either Cys¹⁴-Nem or Cys²⁶-Nem, it was deduced

that the triply reduced/alkylated peptide contained an intact Cys¹⁴-Cys²⁶ (Cys3-Cys5) disulfide bridge. As Cys²⁹-Nem was observed upon CID of the four Cys-Nem containing paralithocin 1, it was further deduced that a Cys¹⁹-Cys²⁹ (Cys4-Cys7) disulfide existed in the native peptide. The fully reduced and alkylated paralithocin 1 ([M+5H]⁵⁺ at *m/z* 1018.0175) produced a spectrum where several y-ions were recorded upon CID (Figure 3e). Thus, the coupling pattern of disulfide bridges in paralithocin 1 was Cys1-Cys8, Cys2-Cys6, Cys3-Cys5, and Cys4-Cys7.

The native paralithocin 2 ([M+5H]⁵⁺ at *m/z* 1010.0416), produced b₁⁺-b₅⁺ and y₆²⁺-y₁₂²⁺ ions upon CID, in accordance with intact disulfide bridges at Cys⁶ and Cys³⁵, respectively. The chromatograms of paralithocin 2 with one, two or three reduced and alkylated Cys-Cys bond all suggest that minor disulfide scrambling has occurred, as two peaks are observed in each chromatogram. Following partial reduction, paralithocin 2 + 2×Nem ([M+5H]⁵⁺ at *m/z* 1060.4630) produced b₂⁺ to b₁₀⁺ upon CID, which indicated Cys⁶-Nem. Singly (y₁ to y₇) and doubly (y₈ to y₁₅) charged y-ions were also recorded, which is in accordance with Cys³⁵-Nem (Table S4). Hence, in the native paralithocin 2 there was a Cys⁶-Cys³⁵ (Cys1-Cys8) disulfide bridge. The reduction and alkylation of two Cys-Cys in paralithocin 2 gave a compound observed as [M+5H]⁵⁺ at *m/z* 1110.8844. Upon CID, b₂⁺ to b₁₀⁺ ions were recorded, which indicated the previously identified Cys⁶-Nem and an intact disulfide at Cys¹¹ (Cys2), and the series y₆²⁺ to y₁₆²⁺, which indicated Cys³²-Nem (Cys7). The position of the second Cys-Nem introduced in this reduction and alkylation step was not identified, but its location at Cys¹¹ and Cys³¹ can be excluded, leaving Cys¹⁶, Cys²¹ and Cys²⁹ as the possible alkylation sites. Next, paralithocin 2 with three Cys-Cys bonds reduced and alkylated ([M+5H]⁵⁺ at *m/z* 1161.3082) underwent CID. The spectrum contained peaks corresponding to b₂⁺ to b₁₄⁺ ions, strongly indicating a Cys¹¹-Nem, and peaks corresponding to y₇²⁺ to y₁₈²⁺ ions, which indicated a Cys³¹-

Nem, yielding a Cys2-Cys6 in the native peptide. There were no peaks in the spectrum that corresponded to reduction and alkylation of any of Cys¹⁶ or Cys²⁹, we therefore deduced that an intact Cys¹⁶-Cys²⁹ (Cys3-Cys5) disulfide bridge remained in triply reduced and alkylated paralithocin 2. The disulfide coupling pattern of native peptide was therefore Cys⁶-Cys³⁵ (Cys1-Cys8), Cys¹¹-Cys³¹ (Cys2-Cys6), Cys¹⁶-Cys²⁹ (Cys3-Cys5), and Cys²¹-Cys³² (Cys4-Cys7). A large number of ions were recorded upon CID of the fully reduced and alkylated paralithocin 2, covering almost the entire sequence (Table S4).

The final peptide, paralithocin 3, is 51 aa long, has four disulfide bridges, and has the same motif as paralithocin 1 and paralithocin 2, that is, CXCCXXC, and it was expected that this peptide had the same disulfide bridge coupling pattern as the former peptides. It was, however, difficult to record CID spectra of paralithocin 3 with the same quality, that is, a vast number of ions indicative of the structure, as was obtained upon CID of paralithocins 1 and 2. Native paralithocin 3 ($[M+7H]^{7+}$ at m/z 795.3528) underwent CID and b_2^+ to b_7^+ and y_{50}^{6+} to y_{44}^{6+} were observed, indicating Cys⁸ (Table S5). Ions providing evidence for Cys³⁹ were also recorded, that is, y_2^+ to y_{10}^+ , y_{11}^{2+} , and y_{12}^{2+} . The reduction and alkylation of one Cys-Cys in paralithocin 3 yielded a $[M+7H]^{7+}$ ion at m/z 831.3688. Its CID spectrum showed peaks indicating Cys⁸-Nem (Cys1) by the recorded b_8^+ , b_{10}^{2+} , y_{46}^{5+} to y_{37}^{4+} , and y_{35}^{4+} ions. Furthermore, the recorded y_2^+ to y_9^+ , y_{11}^{2+} , y_{12}^{2+} , and y_{14}^{2+} ions are indicative of Cys³⁹-Nem, suggesting a Cys1-Cys8 bridge in the native peptide. The CID spectra of paralithocin 3 where two or more disulfide bridges are reduced and alkylated were hard to interpret, as very few ions useful for structure characterization were recorded, most ions were of low abundance (Table S5). For (paralithocin 3 + 4×CysNem), the CID spectrum showed peaks corresponding to y_{10}^+ and y_{14}^{2+} ions, weakly indicating Cys³⁶-Nem (Cys7). A b_{15}^{2+} was also recorded, but this is not sufficient evidence to claim a disulfide constituting Cys¹⁷ (Cys2). A series of low abundant y-

ions was observed upon CID of (paralithocin 3 + 6×CysNem), that is, y_2^+ - y_{10}^+ and y_{12}^{2+} - y_{18}^{2+} . These ions suggest Cys³⁹-Nem, Cys³⁶-Nem, and Cys³⁵-Nem, and if the CXCCXXC motif is taken into consideration, this implicates an identical Cys-Cys bridging pattern in paralithocin 3 as for paralithocin 1 and 2. Unfortunately, no b- or y-ions were observed that could add evidence to the anticipated Cys¹⁷-Nem, except the y_{33}^{4+} ion, however, this ion had a mass accuracy of $\Delta m = -7.9$ ppm.

In a peptide having eight cysteines, and where all of them have formed disulfide bridges, there are 105 coupling possibilities. The bridging in paralithocins 1 and 2 were identical, both having a bond connectivity of Cys1-Cys8, Cys2-Cys6, Cys3-Cys5, and Cys4-Cys7, and there is evidence to claim that this also applies to paralithocin 3 (Figure 4). Unwanted disulfide scrambling products were not observed during the fragmentation analysis of the paralithocins. However, paralithocin 1 was observed almost solely as N-terminal acid during the analysis, whereas the amide-carboxylic acid ratio was approximately 8:1 for paralithocin 2 and 2:1 for paralithocin 3. As these peptides contain a consensus CXCCXXC motif, it was anticipated an identical bridging in all three. Disulfide bridges are found to be remarkably conserved between homologous proteins and they are not produced randomly.⁴¹ The folding and correct bridge formation requires the involvement and aid of several proteins. For an organism to express peptides possessing the same motif, it would presumably be more demanding than beneficial to have more than one folding and cysteine oxidation apparatus simultaneously running. Cys-rich AMPs are widely distributed in animals and plants, but although having the same number of cysteine residues, the paralithocins show a cysteine arrangement pattern and disulfide connectivity different from any known Cys-rich AMPs (Table 1). Disregarding the flanking cysteines (Cys1 and Cys8) of the paralithocins, the remaining cysteines fold into a Cys1-Cys5, Cys2-Cys4, and Cys3-Cys6 connectivity, identical to the lobster panusin²³ and the vertebrate

β -defensins and the invertebrate big defensins.⁴² However, homology searches and sequence alignment with selected peptides obtained from these classes reveal no similarities to the paralithocins. The paralithocins 1-3 may therefore be assigned to a new family of antimicrobial peptides within the group of Cys-rich antimicrobial peptides.

Figure 4. Final Cys coupling pattern of paralithocins 1 (P23), 2 (P30), and 3 (P34).

Antibacterial Properties of the Isolated Peptides. The native peptides isolated from *P. camtschaticus* were screened for antibacterial activity against a panel of terrestrial and marine bacterial strains. The paralithocins display in general a low to moderate activity against microorganisms under the testing conditions used (Table 2).

In general, paralithocin 3 was the most potent peptide with minimal inhibitory concentration (MIC) values as low as 12.5 μ M against *C. glutamicum* and some Gram-positive marine bacterial strains. Paralithocin 1 was the least active peptide with MIC values of 50 μ M and upwards. This fact might explain why the peptides (especially paralithocin 1) are present in relatively high concentrations in the hemocyte extracts. According to the UV-Vis chromatogram, the paralithocins are among the major components (with paralithocin 1 being the dominant peptide) in the extract. Furthermore, 52.7% of the EST contigs subjected to bioinformatics analyses corresponded to the paralithocins, with 40% of them corresponding for paralithocin 1 alone. None of the paralithocins displayed any growth inhibition of the terrestrial

strains *Staphylococcus aureus*, *Pseudomonas aeruginosa* and *Escherichia coli* at a concentration of 100 μ M. Most natural AMPs are considered to kill or inhibit bacteria by damaging the outer and/or cytoplasmic membranes. Differences in membrane architecture and/or lipid composition might therefore affect the efficacy of AMPs, resulting in varying AMP susceptibility of different strains. As a response to low temperatures, marine bacteria optimize their membrane fluidity by incorporating long-chain polyunsaturated fatty acids in their membranes,⁴³ a membrane composition that might make the marine bacteria more susceptible to the paralithocins. Furthermore, due to lower growth rate for marine bacteria at low temperatures, a longer incubation period is necessary before any antimicrobial activity can be evaluated *in vitro*. This longer incubation period (72 h at 12 °C versus 24 h at 37 °C), where the AMPs are given time to interact with its target(s), might also lead to lower MIC values against the marine Gram-positive bacteria. Although the paralithocins display low to moderate antibacterial activity in the present study, they might still have an antimicrobial function *in vivo*. The paralithocin producer, the red king crab, is a cold-loving species tolerating water temperatures of -1.7 to +11 °C⁴⁴ and immature crabs have in laboratory studies shown a temperature preference of below 6 °C.⁴⁵ It remains to be studied whether the paralithocins are more potent at temperatures lower than 12 °C.

As shown by MS analysis, the ratio for the C-terminal amidated versus C-terminal acid forms of paralithocin 1 and 3 was reduced during processing and/or storage. The increased proportion of the acid form (with reduced charge) might be responsible for the low activity detected for (especially) paralithocin 1. A net positive charge of AMPs is known to facilitate electrostatic interactions with the negatively charged membrane and/or cell wall structures of bacteria.⁴⁶ For many other peptides, a C-terminal amide is even required for full biological activity.³³ The paralithocins might also act synergistically to fight infectious pathogens, as

shown for other arthropods.⁴⁷ SPE extracts from *P. camtschaticus* hemocytes have previously shown to be antibacterial at protein concentrations as low as 31.25 µg/ml, even against *E. coli*.⁴⁸ Assuming that the average molecular weight of the peptides in the extract were around 5 kDa, the observed MIC is close to 6 µM, a more than 16-fold lower MIC compared to the most potent paralithocin.

The reference AMP, cecropin P1, was active against all test bacteria with MIC values ranging from 0.8 to 100 µM. In contrast to the disulfide-rich paralithocins, cecropin P1 is a linear, α -helical AMP with no disulfide bridges, known to affect bacterial membranes (Kjuul et al., 1999). Of note, whereas the paralithocins show increased activity against the marine Gram-positive bacteria, cecropin P1 display a reduced and moderate activity, indicating different mechanism(s) of action between the two types of peptides.

Although the antimicrobial activity of the paralithocins are moderate-low, the peptides are present (and expressed) in relatively high concentrations indicating they are of importance for the animal. As shown for many other AMPs, such molecules may also act as immune effectors *in vivo*.⁴⁹ AMPs containing eight Cys residues have also shown to have other functions. For instance, the insect-derived drosomycin and the structurally related plant defensins, all having the cysteine-connectivity of Cys1-Cys8, Cys2-Cys5, Cys3-Cys6, and Cys4-Cys7, display multiple biological activities. Although some of them display antibacterial activity, their antimicrobial activity is mainly directed against fungi^{50, 51} and drosomycin also display antiparasitic activity.⁵² In addition, some of the plant defensins inhibit α -amylases⁵³ and proteases,⁵⁴ and some are shown to block calcium,⁵⁵ potassium,⁵⁶ and sodium channels.⁵⁷

Table 2. Antibacterial Activities of the Native Paralithocins and the Reference Peptide Cecropin P1 Against Terrestrial and Marine Bacteria.

Minimal inhibitory concentrations, MIC (μ M) ^a											
Bacterial strains ^b	Gram-negative					Gram-positive

^a MIC was determined as the lowest concentration of peptide causing an optical density less than 50% of the growth control. ^b *E.c.*, *Escherichia coli*; *P.a.*, *Pseudomonas aeruginosa*; *Y.u.*, *Yersinia ruckeri*; *L.a.*, *Listonella anguillarum*; *A.s.*, *Aeromonas salmonicida*; *C.g.*, *Corynebacterium glutamicum*; *S.a.*, *Staphylococcus aureus*; *C.ma.*, *Carnobacterium maltaromaticum*; *C.mo.*, *Carnobacterium mobile*; *C.d.*, *Carnobacterium divergens*; *C.f.*, *Carnobacterium funditum*. ^c n.t., not tested.

In summary, the three paralithocin peptides are the first AMPs isolated from the red king crab. The three peptides are all cationic and contain eight cysteines, which are engaged in four intramolecular disulfide bridges in the native configuration. Although these peptides only possess weak antibacterial activity *in vitro*, the concentrations at sites of infections in the animal might be much higher. In addition, the high redundancy of the EST in the library indicates their importance in response to bacterial LPS. Nevertheless, their primary structure and disulfide arrangement is unique and could serve as a template for finding other, more potent AMPs in other species. Because these peptides seem to be produced in relatively high concentrations *in vivo*, we hypothesize that they play an important role in the animal's host defense, and have other biological functions which remain to be explored. Due to their unique cysteine motifs and disulfide arrangement, the paralithocins may be assigned to a previously unknown family of AMPs. Further studies should be directed towards studying other biological functions (such as antifungal, chitin-binding, and protease inhibitor activity) of these peptides. Furthermore, the

evolutionary relationship between the paralithocins and other Cys-rich peptides should be elucidated.

EXPERIMENTAL SECTION

Collection of Animals and Sample Preparation. Live specimens (22 adult animals, average weight ca. 1500 g, all males) of the red king crab, *Paralithodes camtschaticus*,⁵⁸ were collected using crab pots in Varangerfjord, Finnmark, Norway. The animals were kept in tanks with circulating seawater until hemolymph collection. Hemolymph was collected from 10 animals by entering the unsclerotized membrane at the base of the chelipeds and pereopods, as previously described.³² The hemolymph (1925 mL in total) was immediately centrifuged at 800 x g at 4 °C for 20 min to separate the hemocytes from the plasma. The hemocytes were subsequently frozen at –80 °C, lyophilised, pooled and kept frozen at –20 °C until peptide extraction and purification. Six animals were used for nucleic acid extractions. Lipopolysaccharide (LPS), purified from *Aeromonas salmonicida*,⁵⁹ was diluted to a concentration of 1 mg/mL in PBS buffer, adjusted to 1000 mOsmol/kg, and injected into four animals with a dose of 200 ng/g crab. The injection was done with a G syringe through the unsclerotized membrane at the base of the chelipeds and pereopods. Two control animals were treated identically, but injected with only PBS. The hemolymph was collected 42 h after injection and the hemocytes were isolated as described above.

Extraction and Purification of Antimicrobial Peptides. Freeze-dried hemocytes (9.92 g) were extracted as previously described.³² Briefly, the material were extracted with 10 volumes (v/w) of 60% (v/v) MeCN (HPLC-grade, SDS) containing 0.1% trifluoroacetic acid

(TFA; Fluka Chemie AG) for 24 h at 4 °C. The supernatant was collected, stored at 4 °C, and the residue was extracted once again using the same conditions. The combined supernatants were incubated at –20 °C for 1-2 h to allow an organic and an aqueous phase to be partitioned. Due to high salt content (from the sample) and high MeCN content, the extraction medium precipitates high molecular weight proteins and proteolytic enzymes. The aqueous phase was collected, and dried in a vacuum centrifuge (Maxi Dry Lyo, Heto Laboratories). The material (3.58 g) was solubilised in 0.05% TFA to a concentration of 100 mg/mL. The extract was applied onto a reversed-phase solid phase extraction (SPE) cartridge,³² and the peptides were eluted with MeCN-aqueous TFA (0.5%; 40:60, v/v). The peptide containing eluate was dried under vacuum, resuspended in 0.05% TFA, and subjected to preparative reversed-phase high performance liquid chromatography (RP-HPLC). The HPLC system (Waters Associates) consisted of a 600E pump, a 717 autosampler, a 2996 photodiode array (PDA) detector, and a SunFire Prep C₁₈ (90Å; 5 µm; 10 x 250 mm) column. Elution was performed with a linear gradient running from 0 to 40% MeCN in 0.05% TFA over 75 min, with a flow rate of 2 mL/min. Absorbance was recorded in the range of 200-400 nm, and peak fractions were collected manually. Fractions were dried under vacuum and reconstituted in 200 µL distilled H₂O, and aliquots (50 µL) of the fractions were tested for antibacterial activity against *Listonella anguillarum* and *Corynebacterium glutamicum*. Active fractions were analyzed by electrospray ionization MS (ESI-MS) to determine their purity. Fractions with impurities were subjected to a second round of chromatography on a Symmetry 300 C₁₈ column (Waters; 300 Å; 5 µm; 4.6 x 250 mm) and eluted under the same experimental conditions as described in step 2, but with a flow rate of 1.0 mL/min. Fractions were collected manually and submitted to ESI-MS analysis.

Mass Spectrometry Analysis. Peptide purity was analyzed using a Waters Micromass ZQ single quadrupole instrument equipped with an ESI ion source (Micromass Ltd) controlled by the MassLynx v4.1 software (Micromass). Samples were dissolved in H₂O and MeOH (50:50 v/v) containing 0.02% formic acid. Spectra were recorded in positive ion mode with a spray voltage of 3 kV and a cone voltage of 30 V. Samples were infused with a flow rate of 10 µL/min. Nitrogen was used as desolvation gas (flow 1200 L/h) and cone gas (flow 40 L/h), and the ionization temperature was set to 110 °C. The spectra were recorded in the continuum mode of acquisition and the quadrupole was scanned from m/z 100 to 2000 at 4 s per scan. MALDI-TOF analyses of reduced, alkylated and enzyme digested native peptides were done at the Department of Cell and Molecular Pharmacology, Medical University of South Carolina, United States. The top down MS/MS analysis was combined with the ProSightPTM program made by the Kelleher Group of the Department of Chemistry, University of Illinois, USA.^{60, 61}

Amino Acid Analysis and Sequencing. The HPLC peak fractions P23, P30, and P34 were dissolved in 6 M HCl and hydrolyzed in vacuum for 20 h at 110 °C. Phenylisothiocyanate was added for amino acid derivatization, and phenylthiocarbamyl residues were separated and analyzed on an automatic amino acid analyzer (Model 421, Applied Biosystems, Perkin Elmer). The instrument was calibrated with 100 pmol of phenylthiohydantoin amino acid standards. Edman degradation of native and alkylated (4-vinyl-pyridine) peptides was done at the Biotechnology Centre of Oslo (University of Oslo, Norway), and was performed on a protein micro sequencer model 477A with a 120A PTH analyzer (Applied Biosystems) and a HP 241 Protein Sequencer (Hewlett-Packard).

Tissue Collection and RNA Extraction. The hemocytes from LPS challenged and non-challenged king crabs were sampled and subjected to RNA extraction (see below). Briefly, one mL of hemolymph was centrifuged at 13,200 rpm for 1 min, the serum was discarded and the pelleted hemocytes suspended in 1 ml of Qiazol (Qiagen). To ensure complete lysis, the hemocytes were squeezed through a 0.8 mm x 4.0 mm needle and left on ice for 5 min. RNA was purified according to the manufacturer's protocol (Qiagen), and dissolved in 50 μ L 1mM Na-citrate, pH 6.4 (Ambion). RNA quantity, purity and integrity was verified spectrophotometrically (A260/A280) and by 1% agarose gel electrophoresis. The two samples containing the highest RNA concentration, were pooled and stored at -80°C until used.

cDNA Library Construction and Sequence Analysis. A hemocyte cDNA library from LPS-injected animals was constructed with pooled total RNA from hemocytes of two king crabs using the SMART cDNA library constructions kit (Clontech) following the manufacturer's instructions for long distance PCR. The cDNA was ligated into the λ TriplEx2 arms and packaged, using the Gigapack III Gold packaging system (Stratagene). *Escherichia coli* strain BM25.8 was used to convert the λ TriplEx2 phage into plasmid pTriplEx2 by mass excision and circularization. The converted library with the highest titer (originated from LPS injected animals) was then plated and grown overnight at 31°C on 10 LB agar plates containing 50 $\mu\text{g/mL}$ carbenicillin each. Three hundred and eighty-four randomly selected clones from this library were individually picked (Genetix colony picker robot), cultured in microtiter plates and subsequently sequenced from the 5' end with the Clontech pTriplEx2 forward primer (5'-AGCTCCGAGATCTGGACGAGC-3'). The library was amplified in B25.8 following the manufacturer's protocol (SMART cDNA library construction kit) and stored with 0.3 % CHCl_3 at 4°C and added 7% DMSO to the tubes for storage at -80°C .

Determination of Disulfide Connectivity

Chemicals and Equipment. Tris(2-carboxyethyl)phosphine hydrochloride (TCEP; 0.5 M in H₂O), citric acid monohydrate, trisodium citrate dihydrate, *N*-ethylmaleimide (Nem), MeOH, and formic acid were purchased from Sigma-Aldrich. Fraction collection (T-piece 9:1 flow splitting post column) and HRMS/MS was conducted on an Accela 1250 HPLC pump and Accela Open autoinjector coupled through an ESI ion source to a QExactive mass spectrometer from Thermo, controlled by XCalibur 2.3. The mass spectrometer was operated in full scan mode (m/z 750-1250) during semipreparative HPLC, with spray voltage 3 kV, desolvation temperature 275 °C, and desolvation gas (nitrogen) at 40 L/h. A Polaris C18A (50 x 2 mm) from Agilent reversed-phase HPLC column was used for all separations. The mobile phase consisted of A: 0.1% formic acid in H₂O, B: MeOH, and a linear gradient 5-30% B over 45 min was used to elute the peptides.

Partial Reduction and Alkylation. The peptides, 50 µL of an approximately 50 µg/mL solution, were incubated with 10 µL TCEP (1 mM) in 0.25 M citric acid buffer (pH 3.0) at 40 °C for 5 min, then 10 µL Nem (40 mM in the same buffer) was added and the reaction proceeded for 30 min at rt.⁶² The sample was then immediately subjected to semipreparative HPLC (V_{inj} : 25 µL) Fractions were collected manually, and fractions containing peptides with four, three, two, one, and zero disulfide bridges were collected. The partial reduction sometimes resulted in one major and one or more minor fractions of the partially reduced peptides. In these cases, all fractions were collected into separate vials. The most abundant fractions were used for further mass spectrometric investigations. The fractions were diluted with MeOH to consist of approximately 50:50 MeOH-aqueous 0.1% formic acid.

Tandem Mass Spectrometry Experiments. High resolution MS/MS was done by infusing the peptide fractions at 5 $\mu\text{L}/\text{min}$. A resolution of 140,000 (@ m/z 200) was used in all experiments. For full scan experiments (determination of MW and MI), 30 spectra were recorded, and 100-250 spectra were recorded per sample for MS/MS experiments. A normalized collision energy (NCE) of 30% was applied in the higher collision dissociation (HCD) cell for $[\text{M} + 5\text{H}]^{5+}$ precursor ions, NCE = 25% for $[\text{M} + 6\text{H}]^{6+}$ and NCE = 20% for $[\text{M} + 7\text{H}]^{7+}$. The quadrupole was operated with an isolation width of 4 Th.

Data File Conversion and Data Interpretation. The recorded .raw files were converted to mzXML by MassMatrix Mass Spectrometric Data File Conversion Tools 3.9 (www.massmatrix.org). To interpret all spectra, mMass 4.5.1 was used.⁶³⁻⁶⁵ The program was slightly rewritten in Python 2.7 (www.python.org) to enable the identification of ions resulting from S-S cleavages, that is, $[\text{y}_n \pm \text{H}/\text{SH}]$ and $[\text{b}_n \pm \text{H}/\text{SH}]$ ions. As the most abundant isotopomers all were introduced to the HCD cell, this was exploited in structure characterization. The m/z of a monoisotopic ion was calculated by mMass, and during the interpretation of the spectra the presence of isotopomers (and the isotope distribution pattern), along with the recorded mass accuracy of the monoisotopic ion, was used to determine whether a recorded ion was due to an actual dissociation.

Bacterial Strains and Antibacterial Activity Testing. A total of 11 bacterial strains were tested for their susceptibility to the isolated peptides. The Gram-positive bacteria *C. glutamicum* (ATCC 13032) and *Staphylococcus aureus* (ATCC 9144), and the Gram-negative bacteria *E. coli* (ATCC 25922) and *Pseudomonas aeruginosa* (ATCC 25853) were maintained

in culture at 37 °C. Three marine Gram-negative and fish pathogenic strains, namely *L. anguillarum* (AL104), *A. salmonicida* (AL2020), and *Yersinia ruckeri* (CCUG 14190), and five marine Gram-positive *Carnobacterium* strains; *C. maltaromaticum* (CCUG 34645), *C. mobile*, *C. divergens* and *C. funditum* (CCUG 34644) were all grown at 12 °C. All bacteria were grown in Mueller Hinton Broth (Difco Laboratories), except the marine Gram-positive *Carnobacteria* strains which were grown in modified Tryptic soy broth with added glucose (5%) and 2% NaCl. *L. anguillarum* and *A. salmonicida* were provided by the Norwegian Veterinary Institute (Oslo, Norway), whereas the marine Gram-positive strains were a gift from Prof. E. Ringø, Norwegian College of Fishery Science, UiT The Arctic University of Norway (Tromsø, Norway).

The antibacterial activities of the obtained HPLC fractions against two bacterial strains (*L. anguillarum*, and *C. glutamicum*) were determined as previously described.⁶⁶ Briefly, 50 µL of test material were incubated with an equal volume of actively growing bacteria in 96 well Nunc-plates. The starting concentration of bacteria were 5×10^3 cells per well, and the test strains were incubated at 37 °C for 24 h, whereas the marine bacteria were incubated at 12 °C for 72 h. Bacterial growth was monitored using a Bioscreen C microbiology reader (Labsystems Oy). Cecropin P1⁶⁷ (0.5 µg/mL) was used as a positive control for all strains, while distilled H₂O was added in the growth control. Antibacterial activity was determined when the optical density (OD) of the growth control (bacteria plus water) reached an absorbance of approximately 0.3. Fractions were regarded as active when the OD was less than 50% of the growth control. Serial two-fold dilutions (concentrations ranging from 1.6 to 100 µM) of purified, native peptides were made in double distilled H₂O and tested for activity against four terrestrial and eight marine bacterial strains according to the method described above. For selected marine strains, the peptide concentration of P23 was raised to 200 µM. The peptide content was determined by weighing mg amounts of purified samples. The minimal inhibitory

concentration (MIC) was defined as the lowest concentration of peptide causing an OD less than 50% of the growth control after 24 and 72 h of incubation for terrestrial and marine bacteria, respectively.

Bioinformatics and Sequence Analysis. Sequences were submitted to BLASTX and BLASTN⁶⁸ searches against GenBank provided by the NCBI server (www.ncbi.nlm.nih.gov/BLAST). Sequence redundancy was determined by contig analysis using CAP3⁶⁹ through the GOCART tool available at www.marinegenomics.org.⁴ AMP similarity searches were performed against APD3, the Antimicrobial Peptide Database (aps.unmc.edu/AP/main.html);⁷⁰ DBAASP, Database of Antimicrobial Activity and Structure of Peptides (dbaasp.org/home);⁷¹ DRAMP, Data Repository of Antimicrobial Peptides (dramp.cpu-bioinfor.org);⁷² and CAMP_{R3}, Collection of Anti-Microbial Peptides (www.camp.bicnirrh.res.in/index.php).⁷³ Isoelectric points was calculated using the Expert Protein Analysis System (ExPASy; www.expasy.org) proteomics server of the Swiss Institute of Bioinformatics whereas theoretical monoisotopic masses were calculated using the ChemCalc online prediction software (<http://www.chemcalc.org/>).⁷⁴ Signal peptides was predicted by the SignalP 4.1 Server (www.cbs.dtu.dk/services/SignalP).⁷⁵ Nucleic acid sequences were edited and analyzed with the BioEdit program (www.mbio.ncsu.edu/BioEdit/bioedit.html) and uploaded to NCBI GenBank.

ACKNOWLEDGEMENTS

The work was financed by the Research Council of Norway (grants no. 184688/S40 and 208546/O30), Tromsø Research Foundation, and UiT The Arctic University of Norway. First, we would like to thank Professor P. S. Gross (deceased 2008) for the collaboration in this project and the opportunity to stay and perform part of this project in his laboratory at Marine Biomedicine and Environmental Sciences Center, Medical University of South Carolina (MUSC), SC 29412, USA. We would also like to thank K. Schey and J. Bethard, Department of Molecular and Cellular Pharmacology, Medical University of South Carolina, Charleston, SC, USA for their assistance in confirming the native peptides primary sequences. E. M. Nilssen, UiT The Arctic University of Norway, Tromsø, Norway, and the crew on the research vessel F/F Johan Ruud are gratefully acknowledged for sampling of king crabs.

Table S5. Collision induced dissociation (CID) fragments obtained by MS/MS sequencing of Native and partially alkylated Paralithocin 3	11
Figure S1. Consensus nucleotide and amino acid sequences of contigs.....	17
Figure S2. TIC of paralithocin 1 (P23):	19

Table S1. Amino Acid Composition of P23, P30, and P34

Table S1. Amino Acid Composition of P23, P30, and P34, Antimicrobial Peptides isolated from *P. camtschaticus* Haemocytes. Values shown are in Molecular Percentage.

Amino acid	Composition (mol %)		
	of		
	P23	P30	P34
Aspartic acid/asparagine ^a	4.0	7.5	8.8
Threonine	0.0	4.3	2.3
Serine	22.5	4.3	11.0
Glutamic acid/glutamine ^a	7.0	8.1	8.9
Proline	5.7	21.2	16.1
Glycine	13.6	11.4	9.1
Alanine	6.1	12.3	10.7
Valine	0.0	4.3	2.9
Cysteine ^b	18.9	3.8	4.5
Methionine ^b	0.0	0.0	0.0
Isoleucine	8.0	3.1	5.8
Leucine	0.0	2.9	3.0
Tyrosine ^b	1.0	6.1	0.0
Phenylalanine	0.0	0.0	0.7
Lysine	3.3	2.7	3.1
Histidine	0.0	0.6	2.6
Arginine	9.9	7.4	10.5
Tryptophan ^c	-	-	-

^a These amino acids could not be differentiated one from the other. ^b Partially destroyed during acid hydrolysis. ^c Not determined due to destruction during acid hydrolysis.

Table S2. Overview and Redundancy of Contigs obtained from an EST Library

Table S2. Overview and Redundancy of Contigs obtained from an EST Library originated from Hemocytes of two Red King Crabs 42 h post injection of *A. salmonicida* LPS. Contigs 2, 11 and 16 were selected for further Analysis and are High lightened in grey.

Contigs	Redundancy of 374 EST	Percent (%)	Expected redundancy of 10 000 EST
1	3	0,8	80,2
2	150	40,1	4010,7
3	4	1,1	107,0
4	2	0,5	53,5
5	18	4,8	481,3
6	2	0,5	53,5
7	17	4,5	454,5
8	3	0,8	80,2
9	3	0,8	80,2
10	2	0,5	53,5
11	16	4,3	427,8
12	3	0,8	80,2
13	2	0,5	53,5
14	4	1,1	107,0
15	2	0,5	53,5
16	31	8,3	828,9
Singletons	112	29,9	2994,7
	374	100,0	10000,0

Table S3. Masses of the Native Paralithocins

Table S3. Masses and calculated Properties of the Native Paralithocins.

Peptide	C-term	# aa	Monoisotopic mass (Da)			Net charge ^d
			Calcd. ^a	Exp. ^b	Δm^c	
Paralithocin 1	-NH ₂	38	4075.6231	4075.6248	0.0017	+4.0
	-COOH		4076.6072	4076.6044	0.0028	+3.0
Paralithocin 2	-NH ₂	47	5045.1668	5045.1705	0.0037	+4.0
	-COOH		5046.1508	5046.1480	0.0028	+3.0
Paralithocin 3	-NH ₂	51	5559.4239	5559.4226	0.0013	+5.1
	-COOH		5560.4080	5560.4052	0.0028	+4.1

^aValues calculated based on cysteines in oxidized forms. ^bMasses calculated from monoisotopic m/z [M+nH]ⁿ⁺ values obtained from ESI-Q-TOF MS spectra. ^cThe absolute difference between the calculated and experimental monoisotopic mass. ^dNet charge at pH 7 was calculated using Innovagen's peptide property calculator (<http://pepcalc.com>).

Table S4. Collision induced dissociation (CID) fragments obtained by MS/MS sequencing of native and partially reduced/alkylated Paralithocin 2

Table S4. Collision induced dissociation (CID) Fragments obtained by MS/MS sequencing of Native and Partially reduced/alkylated Paralithocin 2. (A) Native, intact Paralithocin 2, (B) Partially reduced and alkylated with 2 x NEM, (C) Partially reduced and alkylated with 4 x NEM, (D) Partially reduced and alkylated with 6 x NEM, (E) Completely reduced and alkylated with 8 x NEM.

Table S5. Collision induced dissociation (CID) fragments obtained by MS/MS sequencing of Native and partially alkylated Paralithocin 3

Table S5. Collision induced dissociation (CID) fragments obtained by MS/MS sequencing of Native and partially alkylated Paralithocin 3. (A) Native, intact paralithocin 3, (B) Partially Reduced and alkylated with 2 x NEM, (C) Partially reduced and alkylated with 4 x NEM, (D) Partially reduced and alkylated with 6 x NEM, (E) Completely reduced and alkylated with 8 x NEM.

(A) Paralithocin 3. Native. 4 cystine brigdes. [M+7H]⁷⁺ @ m/z 795.3528

Figure S1. Consensus nucleotide and amino acid sequences of contigs from EST library of king crab hemocytes; (A) contig 2 corresponded to paralithocin 1, (B) contig 16 corresponded to paralithocin 2 and (C) contig 11 corresponded to paralithocin 3. Pre-sequences are underlined and putative mature amino acid sequences are in bold. Cys residues are shaded in grey. Start and stop codons are doubled underlined and polyadenylation signal sequence (aataa) are shaded in black. The C-terminal amino acids cleaved off in the mature peptides are boxed. The sequences have been submitted to the Gene Bank with accession numbers MF919584 (paralithocin 1), MF919585 (paralithocin 2), and MF919586 (paralithocin 3).

Figure S2. TIC of paralithocin 1 (P23):

Figure S2. TIC of paralithocin 1 (P23): (a) intact, (b) one reduced Cys-Cys, (c) two reduced Cys-Cys, (d) three reduced Cys-Cys, (e) all reduced Cys-Cys; paralithocin 2 (P30): (f) intact, (g) one reduced Cys-Cys, (h) two reduced Cys-Cys, (i) three reduced Cys-Cys, (j) all reduced Cys-Cys; paralithocin 3 (P34): (k) intact, (l) one reduced Cys-Cys, (m) two reduced Cys-Cys, (n) three reduced Cys-Cys, (o) all reduced Cys-Cys. Regarding monoreduced paralithocin 1 (b) a contaminant of m/z 867.3, which is similar in mass to $[M + 5H]^{5+}$ of paralithocin 1, was observed throughout the chromatographic run, which explain the poorly defined shape of the peak in question (t_R 10.25 min). The TICs were recorded by an API4000 triple quadrupole mass spectrometer from ABSciex.
